

BOTTOM LINE RECOMMENDATIONS:

Urinary Tract Infection

UTI is among the most common serious bacterial infections seen in infants and children. UTI with fever is indicative of an upper tract infection/pyelonephritis, as opposed to afebrile cystitis. It is important to diagnose and empirically treat febrile UTIs in infants and children, as delayed treatment may increase the risk of bacteremia. There are a number of risk factors associated with increased rates of UTI in young children such as age, gender and height of fever. An [evidence-based decision tool](#) has been developed to assess risk factors and help with urine result interpretation.¹

CLINICAL SIGNS AND SYMPTOMS

- › Infants and/or non-verbal children may have fever without another apparent source, increased crying, vomiting, poor feeding and/or other non-specific symptoms. ([See TREKK Recommendations for Fever in Young Infants](#))
- › Children greater than 2 years old typically have urinary symptoms, abdominal/flank/back pain, new incontinence, with or without fever.

RECOMMENDED TESTING

- › A mid-stream urine sample can sometimes be obtained in young infants using bladder stimulation such as the Clean Catch or [Quick Wee method](#).²
- › If a mid-stream sample cannot be obtained, screen infants greater than 2 months old with an adhesive bag for collection of urine.
- › If the bag sample is positive, then a catheter (or suprapubic aspirate) sample **MUST** be obtained for cultures to be sent.
- › A mid-stream urine sample may be sent for culture; a bag sample should **NEVER** be sent for culture.
- › Infants (greater than 2 months old) and children with a clear viral syndrome such as bronchiolitis should have a urinalysis and microscopy sent **ONLY** if there is clinical suspicion of UTI.
- › Consider gonorrhea, chlamydia, and HSV testing if there is a possible/confirmed history of a sexual encounter and dysuria.
- › Urine cultures should be sent to the laboratory as soon as possible or **stored at refrigerator temperature** to avoid false positive results.

Recommended Testing	Dipstick urinalysis	Microscopy	Urine culture	Blood work: CBC and differential, blood culture, urea, creatinine
2 months old – 2 years old and/or non-verbal with fever without source (greater than 39°C)	Screen urine with dipstick. If leucocyte esterase, nitrites and bacteria negative, UTI is ruled out.	Yes, if dipstick/urinalysis positive	No - if urinalysis and microscopy is normal Yes - if urinalysis or microscopy is abnormal	Yes - if infant appears unwell* (i.e. poor feeding, persistent irritability, vomiting)
Greater than 2 years old and verbal with complaints related to urinary tract and fever				Yes - if child appears unwell*
Greater than 2 years old and verbal with complaints related to urinary tract and no fever				No – bloodwork is not required in uncomplicated afebrile cystitis

*Refer to [TREKK Sepsis BLR and PedsPac](#) for infants/children who remain unwell and/or have signs of hypoperfusion.

A lumbar puncture should be performed in any infant/child with clinical signs/symptoms of meningitis.

DIAGNOSIS

- › Urinalysis and microscopy results suggestive of UTI are:
 - › Leucocyte Esterase positive, **AND/OR**
 - › Nitrite positive, **AND/OR**
 - › Greater than 5 WBC/high power field on microscopy, **AND/OR**
 - › Bacteria on microscopy (catheter or suprapubic aspirate sample)
- › If the urinalysis and microscopy are negative in an infant greater than 2 months old, the risk of UTI is less than 1%.

INTERPRETING URINE CULTURE RESULTS

- » Bacterial growth usually takes 24 hours with susceptibility testing and final identification available 24-48 hours later.
- » UTIs typically have growth of a single uropathogen with significant growth being at least:
 - » Greater than or equal to 5×10^7 colony forming units (CFU)/L (50×10^6 CFU/L) from a catheter/suprapubic aspirate specimen, **OR**
 - » Greater than or equal to 10×10^7 CFU/L (100×10^6 CFU/L) from a midstream urine specimen
- » Confirm the diagnosis of UTI in an infant/child with **BOTH** a **POSITIVE** urinalysis and/or microscopy **AND** a **POSITIVE** culture. This is especially important if the colony count is 50×10^6 CFU/L as positive culture in the absence of positive urinalysis/microscopy likely indicates contamination at the lower end of bacterial colony growth.

EMPIRIC THERAPY FOR SUSPECTED URINARY TRACT INFECTION

- » Healthy infants and children greater than 2 months old may be treated as outpatients with oral antibiotics if they are alert, well-appearing, hydrated, can tolerate oral medication and appropriate follow-up is assured.
- » In a first febrile UTI, the most likely bacteria is *E. coli*.
- » If possible, choose an antibiotic with less than 10% resistance to *E. coli* on the most recent local antibiogram available.
- » For children with a history of previous UTIs or known genitourinary abnormalities, empiric therapy should be determined by the result of the most recent urine culture available.
- » Nitrofurantoin should **ONLY** be prescribed to treat afebrile cystitis in the adolescent age group (i.e. not in younger children or febrile UTI).

Age	Antibiotic	Disposition
Greater than 2 months old and well-appearing	Oral Antibiotics <ul style="list-style-type: none"> • Cephalexin 75-100 mg/kg/day divided TID or QID (max 4000 mg/day, or 1000 mg/dose) • TMP-SMX 8-12 mg of TMP component/kg/day divided BID (usual max 320 mg TMP/day; may increase to 640 mg TMP/day) • Cefixime 8 mg/kg/day divided once daily (max 400 mg/day). (Note: broader spectrum but does not cover extended spectrum beta-lactamase and is more likely to induce resistance) 	Discharge home with follow-up assured in 24-48 hours
Greater than 2 months old and unwell OR unable to tolerate oral medication OR IV/IM route preferred	IV/IM Antibiotics <ul style="list-style-type: none"> • Preferred: Gentamicin or Tobramycin 7.5 mg/kg/day divided q24h (max 360 mg/day before levels). (Note: if concern for enterococci, add Ampicillin 100-200 mg/kg/day divided q6h) OR • Ceftriaxone 50-75 mg/kg/day divided q24h (max 2000 mg/dose). (Note: broader spectrum but does not cover extended spectrum beta-lactamase and is more likely to induce resistance) 	Admit to hospital

Note: Refer to local formulary for more specific dosing information

DURATION OF THERAPY

- » For uncomplicated afebrile cystitis: 5 days.
- » For uncomplicated febrile UTI: 7 to 14 days.
- » For complicated febrile UTI (i.e. renal abscess, focal pyelonephritis/nephronia): May be longer than 14 days. Consider referral to Pediatrics, Infectious Diseases, or Urology depending on local practice.

FOLLOW-UP

- » Children who are still febrile or have persistent dysuria after 24-48 hours of appropriate therapy should be reassessed:
 - » Use culture results to verify bacterial susceptibilities
 - » Consider IV antibiotics and admission to hospital
 - » Consider renal ultrasound to detect complications
- » At discharge, communicate to families and primary care physicians that all infants less than 12 months with a first febrile UTI should have a renal and bladder ultrasound to detect significant renal structural abnormalities/high grade vesicoureteral reflux.
- » Discuss modifiable risk factors for urinary tract infections in children and adolescents such as constipation and sexual activity when appropriate.

The purpose of this document is to provide healthcare professionals with bottom line recommendations for the diagnosis and treatment of urinary tract infection in children in the ED. This summary was produced by the urinary tract infection content advisors for TREKK, Drs. Nicole Le Saux and Gina Neto of the Children's Hospital of Eastern Ontario, and uses the best available knowledge at the time of publication. However, healthcare professionals should continue to use their own judgment and take into consideration context, resources and other relevant factors. The TREKK Network is not liable for any damages, claims, liabilities, costs or obligations arising from the use of this document including loss or damages arising from any claims made by a third party. The TREKK Network also assumes no responsibility or liability for changes made to this document without its consent.
